Hydrocarbon traps form where permeable reservoir rocks (carbonates, sandstones) are covered by rocks with low permeability (caprocks) that are capable of preventing the hydrocarbons from further upward migration. Typical caprocks are compacted shales, evaporites, and tightly cemented sandstones and carbonate rocks. The caprock need not be 100% impermeable to water, oil or gas.

1. Introduction. Hydrocarbon migration plays the critical role in connecting sources rocks and traps during hydrocarbon accumulation, including primary and secondary migrations (Hao et al., 2009a; Hindle, 1997; Schowalter, 1979).Accounting for 50% of a rift basin area, the slope belt is regarded as a major target of hydrocarbon migration and accumulation (Zhao et al., 2016).

The geologic elements of a TPS are hydrocarbon source rocks (source rock maturation and hydrocarbon generation and migration), reservoir rocks (quality and distribution), and traps where hydrocarbon accumulates. By using these geologic criteria, 16 conventional total petroleum systems and 18 assessment units in the 13 provinces were defined.

Petroleum trap, underground rock formation that blocks the movement of petroleum and causes it to accumulate in a reservoir that can be exploited. The oil is accompanied always by water and often by natural gas; all are confined in a porous and permeable reservoir rock, which is usually composed of sedimentary rock such as sandstones, arkoses, and fissured limestones and dolomites.
